DS students, welcome to Good Specials Today's video starts with Deep Learning Deep Learning is the first thing What is the slabous of Deep Learning And our deep learning is evolution How our journey has come So let me tell you first Our story was started in artificial intelligence In which we were talking about intelligent systems The machine can be used as a human We started the story of the expert system Robotics So this is the biggest term You can call it an umbrella term It is a company's name It is a toy So you can call it an artificial intelligence After that a department that is what a machine learning So basically what is in the machine learning The future extraction fund That we give the rule based here I mean I gave the rule The rule based on this work What we have done here is to learn from data Then what is the concept of deep learning Where neural networks and complex systems can be designed in a very complex way How we can solve big problems So this is the concept of deep learning And deep learning has multiple technologies Multiple tools Which come in different works Like CNN and convolutional neural networks This is specially for image Where we have the image data We have to classify it And we have to remove the parallel data So we have CNN there Then we have RNN Where we work on sequential data Where data is related to my previous data Like speech So my last word is related to the next word For that RNN Then the transformers Very important transformers We use it today That all our LL models This transformers are models Where we have long range That means I have a long sequential data Parallel processing And on that basis What is the final product that we have left? We have said that the total data So this is the evolution And in the final, the fortuneer is out The legendary fortuneer is out What is that? LL model So what is LLM? The generator that we use on the time of today Gemini iCloud This is all what we have to say So in this way, this is your enhancement So that is why you have to take all these things To advance from basic to basic So here first of all Let me talk about the syllabus So we have the foundation The neural network concept What are the perceptrons? Single layer, multi layer perceptrons And what is the foundation of bias weights? This is a big basic You should know that Because you cannot read the neural network concept Till you don't understand these things And aside from this I will tell you a little bit about mathematics If I say basic to the neural network Or probability, stats, all these things Python, so this is what you should know After that Deep learning In a little bit Deep diving Deep diving will be able to do When you have basic diving Deep diving If you have ever seen this video So what happens in deep diving? The Sundar is going down So just a little bit of a gap And not going down Put all the equipment All the good things are put And then go Trainers go to the train So the same thing I am telling you here So in the college university In the interview You don't ask anywhere This syllabus will help you a lot So we will cover all the topics Activation function, loss function Then the optimization will come in Which is my output How to optimize it? So here Gradient descent is an item Overfitting concept All these things we will have to learn here So we will have to note this After that This is our C&N's full model You should know this C&N's R&N's model And this is the long short term memory concept You should know LSTM Then the transformers' model That is modern AI Where attention, mechanism Which is important to you Which is the architecture And corner, decoder, architecture, parallel processing That is what I should understand And then after that The models come GPDs, bird, fine tuning All of this We have to do one by one So this is the link You will start from basics Then where is the advance level And in the last We have the GN, generator What is the

generator? What is the adversary? What is the losses? Encoder, decoder, latent space Or even object detection Yo, bro If you give a picture Then you have to detect objects Which is car, which is person, which is animal And where is the location of this picture? You will have to remove all these things So in real life application This is the use and time Take any application from medical Take any application In today's time In each place So you have to do it very well And in practical skill I will talk about frame works So TensorFlow And there is a pipe It is a carousel And in implementation We will do all these things And implement the basic problems And some projects Which you can do with it But I will tell you again That directly here Even directly here Whenever you are dev learning So guys First of all, to start with basic Again and again That's why I am telling you Because if you want to do a deep understanding Then this is the way to do it Thank you
